Senior C#/.NET Engineer (m/f/d) Healthcare — Project 30673

Dear Mr Neusser,

Modernising healthcare software while keeping it stable is a task I know from both enterprise development and regulated medical projects. Your assignment combines hands-on C#/.NET engineering with the careful evolution of existing applications. At MAN Truck & Bus, I migrated legacy components to a modular .NET Core platform; at Roche, I developed test and validation approaches for medical and laboratory software. I would bring these complementary perspectives to your client's modernisation work: understanding existing behaviour, making focused changes and checking their effects. The combination of development, reliability and a healthcare context makes this assignment particularly relevant to my experience.

At MAN Truck & Bus, I worked on an enterprise platform whose overall scope covered more than 100 modules. I developed backend components, integrated relational databases and helped evolve the architecture towards maintainable services. My practical experience with asynchronous and parallel processing includes work at MAN, Dynamic Biosensors and Roche, alongside performance optimisation of existing components. For your client, I would use this experience to investigate performance constraints and modernise components while keeping database interaction and application stability in view. Automated tests provide a practical basis for checking changes against established behaviour.

At MAN Truck & Bus, I coached colleagues in design patterns and code reviews and helped align development standards across teams. These discussions made implementation choices understandable and provided a way to share practical knowledge. At Roche, collaboration with developers, quality assurance and domain experts helped connect technical implementation with validation needs. I would bring the same approach to your client's team: discuss changes clearly, use patterns where they solve a concrete problem, and work together on solutions that colleagues can maintain. For me, quality is part of daily engineering work, from the first implementation through review and validation.

I also use AI agents for implementation, testing and code reviews, with systematic checks of generated results. This complements my experience in developing agent-based systems and gives me a practical basis for your requirement to use agentic AI in the development lifecycle. I work in German and English, with English at C1 level. I would welcome a conversation with you about the existing application, the priorities for modernisation and how I can contribute to the assignment.

Yours sincerely,
Stefan Busch
